

COMP 302: Programming Languages and Paradigms

Prof. B. Pientka, McGill University  McGill

Week 3 (Part 1): Induction

Remember ...

Step 1. Define a set of cake slices recursively.

are cake, then both of them put together is still cake :

Our goal this week: Prove that indeed all cakes are tasty!

How? – Induction!

Proofs are all around you!

“On theories such as these, rely, we cannot. Proof, we need. Proof!”

Maybe someone still has memories of McGill?

Inductive Definitions and Proofs by Induction

Recall: Inductive definition of a list

- The empty list `[]` is a list of type `'a list`.
- If `x` is an element of type `'a` and `xs` is a list of type `'a list` then `x::xs` is a list of type `'a list`.
- Nothing else is a list of type `'a list`.

In OCaml, lists are defined as a recursive data type.

```
1 type 'a list =
2   | []
3   | (::) of 'a * 'a list
4
```

How to prove properties about lists?

Analyze their structure!

Recipe for proving properties about lists ...

To prove that a property `P` holds for a list `l`

Base Case: $l = []$

Show $P([])$ holds

Step Case: $l = x :: xs$

IH $P(xs)$

Assume the property `P` holds
for lists smaller than `l`.

Show $P(x :: xs)$ holds

Show the property `P` holds for the
list `x :: xs`.

Example

```
1 (* rev : 'a list -> 'a list *)           1 (* length: 'a list -> int *)
2 let rec rev l = match l with             2 let rec length l = match l with
3   | []    -> []                         3   | [] -> 0
4   | x::l -> (rev l) @ [x]              4   | _ :: xs -> 1 + length xs
```

Theorem. For all l . $\text{length}(\text{rev } l) = \text{length } l$

But what is equality???

- When we say $\text{length}(\text{rev } l) = \text{length } l$, we are *not* saying that these are *the same program!*
- Technically, we should write:
“There exists v and w such that $\text{length}(\text{rev } l) \Downarrow v$ and $\text{length } l \Downarrow w$ and $v = w$ ”
- The notation $e \Downarrow v$ means “ e evaluates to the value v ”.
- We will however write $e = e'$ as an abuse of notation to say “ e and e' evaluate to the same value”.

Let's revisit the example and prove the theorem!

```
1 (* rev : 'a list -> 'a list *)      1 (* length: 'a list -> int *)
2 let rec rev l = match l with          2 let rec length l = match l with
3   | []    -> []                      3   | [] -> 0
4   | x::l -> (rev l) @ [x]           4   | _ :: xs -> 1 + length xs
```

Theorem. For all l . $\text{length}(\text{rev } l) = \text{length } l$

proof by structural induction on l

- base case: $l = []$

$$\text{length}(\text{rev } []) \rightarrow \text{length } [] \rightarrow 0$$

$$\text{length } [] \rightarrow 0$$

- step case $l = x :: xs$

$$\text{IH: } \text{length}(\text{rev } xs) = \text{length } xs$$

$$\text{length}(\text{rev } x :: xs)$$

$$\rightarrow \text{length}(\text{rev } xs @ [x])$$

$$\rightarrow \text{length}(\text{rev } xs) + \text{length}([x]) \quad \text{by lemma: } \text{length } l_1 + \text{length } l_2 = \text{length}(l_1 @ l_2)$$

$$\rightarrow \text{length } xs + 1$$

$$\rightarrow 1 + \text{length } xs \quad \text{by commutativity of } +$$

$$\rightarrow \text{length } (x :: xs)$$

Another example: Do they compute the same value?

```

1 (* rev : 'a list -> 'a list *) 1 (* rev_tr: 'a list -> 'a list -> 'a list *)
2 let rec rev l = match l with 2 let rec rev_tr l acc = match l with
3 | [] -> [] 3 | [] -> acc
4 | x::xs -> (rev xs) @ [x] 4 | x :: xs -> rev_tr xs (x::acc)

```

Theorem. For all lists l . $\text{rev } l = \text{rev_tr } l$ []

TH: $\text{rev } xs = \text{rev-}tr \ xs$ []

RHS: rev-to ($x :: xs$) []

\Rightarrow rev-tr xs $(x :: [])$ (X) Wrong!

Use the next theorem with $\text{acc} = []$

$$(\text{rev } l) @ [] = \text{rev_tr } l []$$

$\Rightarrow \text{rev } l = \text{rev_tr } l []$

Generalize the statement

```

1 (* rev : 'a list -> 'a list *) 1 (* rev_tr: 'a list -> 'a list -> 'a list *)
2 let rec rev l = match l with 2 let rec rev_tr l acc = match l with
3   | []    -> [] 3   | [] -> acc
4   | x::xs -> (rev xs) @ [x] 4   | x :: xs -> rev_tr xs (x::acc)

```

Theorem. For all l, acc , we have that $(rev l) @ acc = rev_tr l acc$

By structural induction on l .

- base case $l = []$

RHS: $rev_tr [] acc \rightarrow acc$

LHS: $(rev []) @ acc \rightarrow [] @ acc \rightarrow acc$

- step case $l = x :: xs$

IH: for all acc , we have that $(rev xs) @ acc = rev_tr xs acc$

RHS: $rev_tr (x :: xs) acc$

$\rightarrow rev_tr xs (x :: acc)$

$\rightarrow (rev xs) @ (x :: acc)$

LHS: $rev (x :: xs) @ acc$

$\rightarrow ((rev xs) @ [x]) @ acc$

$\rightarrow (rev xs) @ ([x] @ acc)$

$\rightarrow (rev xs) @ (x :: acc)$

Take Away

- Inductive definitions such as recursive data types directly give us a way of thinking recursively.
- Inductive definitions give us induction principles
- Recursion and induction go hand in hand.

In: $\text{length}(\text{rev_t t acc}) = \text{length } t + \text{length acc}$

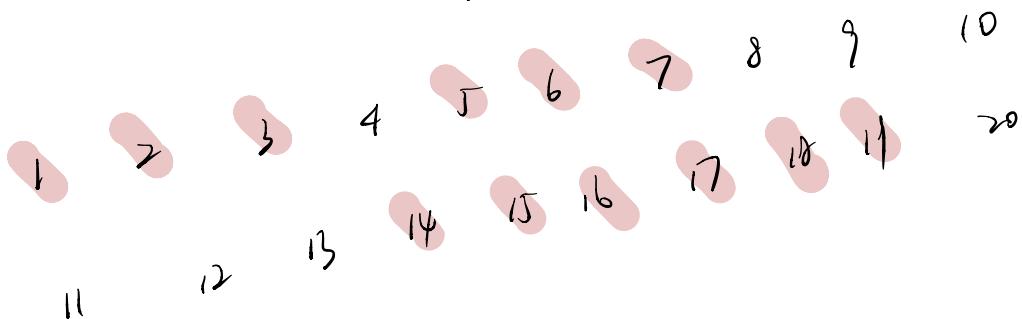

$\text{length}(\text{rev_t child acc}) = \text{length child} + \text{length acc}$

\downarrow

(rev_t child acc)

74

$\text{length } t + \text{length}(\text{child acc})$

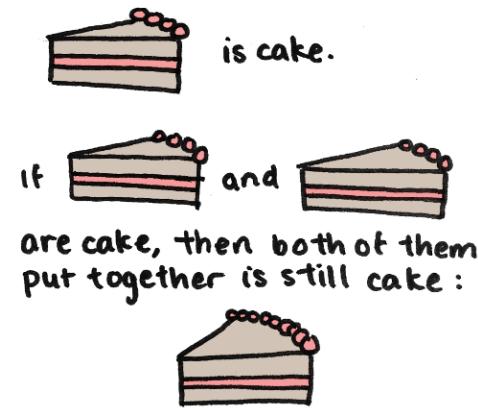

$1 (12 11)$

$1 (12 11)$
 $1 2 (3 11)$

$1 2$

Proving that all cakes are tasty! Rember ...

Step 1. Define a set of cake slices recursively.

This directly gives rise to the following OCaml data type:

```
1 type ingredient = Chocolate | Almonds | Orange
2
3 type cake = Slice of ingredient
4 | Cake of cake * cake
5
6 let tasty_ingredient i = match i with
7 | Chocoloate | Almonds | Orange -> true
8
9 let rec is_tasty c = match c with
10 | Slice _ -> true
11 | Cake (s1, s2) -> is_tasty s1 && is_tasty s2
```

A proof (sort of)

Step 2. Prove that a single piece of cake is tasty.

Step 3. Use the recursive definition of the set to prove that all slices are tasty.

Step 4. Conclude all slices of cake are tasty.

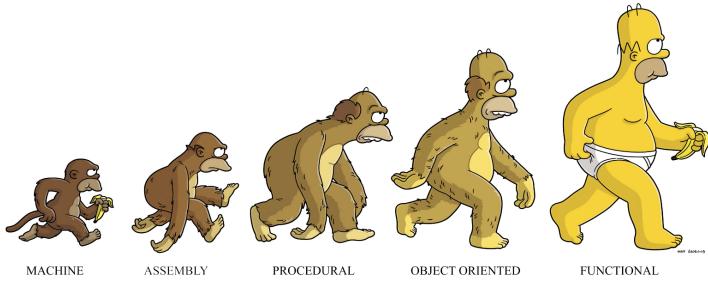

SUPERCHLORINE.com

A better proof

```
1 type ingredient = Chocolate | Almonds | Orange
2
3 type cake = Slice of ingredient
4 | Cake of cake * cake
5
6 let tasty_ingredient i = match i with
7 | Chocoloate | Almonds | Orange -> true
8
9 let rec is_tasty c = match c with
10 | Slice _ -> true
11 | Cake (s1, s2) -> is_tasty s1 && is_tasty s2
```

Theorem. For all cakes c , $\text{is_tasty } c = \text{true}$.

COMP 302: Programming Languages and Paradigms

Prof. B. Pientka, McGill University  **McGill**

Week 3 (Part 2): Induction

Programming with and Reasoning about Binary Trees

Inductive definition of a binary tree

- The empty tree `Empty` is a binary tree, of type `'a tree`.
- If `l : 'a tree` and `r : 'a tree` are binary trees and `v : 'a` is a data item then `Node(l, v, r)` is a binary tree.
- Nothing else is a binary tree.

How to define a recursive data type for trees in OCaml?

```

1 type 'a tree =
2   | Empty
3   | Node of 'a tree * 'a * 'a tree

```

How to reason inductively about trees?

Analyze their structure!

The recipe

To prove a property $P(t)$ holds for a binary tree $t : \text{a tree}$

Base Case: Suppose $t = \text{Empty}$

Show $P(\text{Empty})$ holds

Step Case: Suppose $t = \text{Node}(l, x, r)$

IH $P(l)$

IH $P(r)$

Show $P(\text{Node}(l, x, r))$ holds

Assume the property P holds
for trees **smaller than t** .

Show the property P holds for the
tree $\text{Node}(l, x, r)$.

Let's prove something

```
1 (* insert: *)  
2 let rec insert (k, v) t = match t with  
3 | Empty -> Node (Empty, (k, v), Empty)  
4 | Node (l, (k', v'), r) ->  
5   if k = k' then  
6     Node (l, (k, v), r)  
7   else  
8     if k < k' then  
9       Node (insert (k, v) l, (k', v'), r)  
10    else  
11      Node (l, (k', v')), insert (k, v) r
```

```
1 (* lookup: *)  
2 let rec lookup k t = match t with  
3 | Empty -> None  
4 | Node (l, (k', v), r) ->  
5   if k = k' then  
6     Some v  
7   else  
8     if k < k' then  
9       lookup k l  
10      else lookup k r
```

Theorem: For any tree t , key k , and data v , $\text{lookup } k (\text{insert } (k, v) t) = \text{Some } v$

By structural induction on tree t

• base : $t = \text{empty}$

$\text{lookup } k \ (\text{insert } (k, v) \ \text{empty})$

$\Rightarrow \text{lookup } k \ (\text{Node}(\text{empty}, (k, v), \text{empty}))$

$\Rightarrow \text{Some } v$

• step : $t = \text{Node}(l, (k', v'), r)$

IH 1 : $\text{lookup } k \ (\text{insert } (k, v) \ l) = \text{Some } v$

IH 2 : $\text{lookup } k \ (\text{insert } (k, v) \ r) = \text{Some } v$

subcase : $k = k'$

$\text{lookup } k \ (\text{insert } (k, v) \ (\text{Node}(l, (k', v), r)))$

$\Rightarrow \text{lookup } k \ (\text{Node}(l, (k, v), r))$

$\Rightarrow \text{Some } v$

subcase : $k > k'$

$\text{lookup } k \ (\text{insert } (k, v) \ (\text{Node}(l, (k', v), r)))$

$\Rightarrow \text{lookup } k \ (\text{Node}(l, (k', v'), \text{insert } (k, v) \ r))$

$\Rightarrow \text{lookup } k \ (\text{insert } (k, v) \ r)$

$\Rightarrow \text{Some } v$

Let's have some delicious cake!

Remember ...

Step 1. Define a set of cake slices recursively.

are cake, then both of them put together is still cake:

This directly gives rise to the following OCaml data type:

```
1 type ingredient = Chocolate | Almonds | Orange
2
3 type cake = Slice of ingredient
4 | Cake of cake * cake
5
6 let tasty_ingredient i = match i with
7 | Chocoloate | Almonds | Orange -> true
8
9 let rec is_tasty c = match c with
10 | Slice _ -> true
11 | Cake (s1, s2) -> is_tasty s1 && is_tasty s2
```

Prove that indeed all cakes are tasty!

How? – Induction!

Proving that all cakes are tasty!

A proof (sort of)

Step 2. Prove that a single piece of cake is tasty.

Step 3. Use the recursive definition of the set to prove that all slices are tasty.

Step 4. Conclude all slices of cake are tasty.

SUPERCHLORINE.com

A better proof

```
1 type ingredient = Chocolate | Almonds | Orange
2
3 type cake = Slice of ingredient
4 | Cake of cake * cake
5
6 let tasty_ingredient i = match i with
7 | Chocoloate | Almonds | Orange -> true
8
9 let rec is_tasty c = match c with
10 | Slice _ -> true
11 | Cake (s1, s2) -> is_tasty s1 && is_tasty s2
```

Theorem. For all cakes c , $\text{is_tasty } c = \text{true}$.

By structural induction on c .

- base : $c = \text{Slice } i$
 $\text{is_tasty } (\text{Slice } i) \rightarrow \text{true}$
- step : $c = \text{Cake } (c_1, c_2)$
IH 1: $\text{is_tasty } c_1 = \text{true}$
IH 2: $\text{is_tasty } c_2 = \text{true}$
 $\text{is_tasty } (\text{Cake } (c_1, c_2))$
 $\rightarrow \text{is_tasty } c_1 \And \text{is_tasty } c_2$
 $\rightarrow \text{true} \And \text{true}$
 $\rightarrow \text{true}$

Take Away

- Inductive definitions such as recursive data types directly give us a way of thinking recursively.
- Inductive definitions give us induction principles
- Recursion and induction go hand in hand.
